UDDEHOLM TOOL STEEL FOR
PVD COATINGS
The best of two worlds
This information is based on our present state of knowledge and is intended to provide general notes on our products and their uses. It should not therefore be construed as a warranty of specific properties of the products described or a warranty for fitness for a particular purpose.

Network of Excellence

Uddeholm is present on every continent. This ensures you high-quality Swedish tool steel and local support wherever you are. We secure our position as the world’s leading supplier of tooling materials.

For more information, visit our website at uddeholm.com

The main reason for coating a tool is to enhance wear resistance, minimise the risk for adhesion and decrease sticking between tool and workpiece. The result is often a combination of increased productivity and a higher quality of processed components.

Surface coating of tool steel has become a common practice, physical vapour deposition (PVD) being the most commonly used technique. The coating is typically a thin ceramic layer (< 4 µm) characterised by very high hardness and low friction.

The efficacy of a PVD-coated tool is strongly dependent on the physical and mechanical properties of the steel. High hardness and compressive strengths are necessary to avoid the “glass-on-snow” effect, where the brittle layer cracks easily over a soft substrate. A high tempering temperature is recommended in order to ensure dimensional stability after the coating process. It is also possible to combine PVD with a plasma nitriding treatment (Duplex) to increase the load-bearing capacity of the coating.

The coating should also be defect-free and with a smooth surface in order to effectively reduce sticking and friction. Tool materials with higher cleanliness and improved polishability can guarantee the homogeneity of the coating and a better surface finish on the components.

Within the tool industry there is no “one solution fits all”. Therefore, it is of paramount importance that material and coating selection goes hand in hand.

The aim with this brochure is to present some combinations of tool steels and PVD coatings that have proven to be highly successful. More detailed information about tool steels and coatings can be found in other technical brochures from Uddeholm and voestalpine eifeler Coating GmbH. For optimization of complex tooling solutions we still recommend you to contact Uddeholm for questions about steels and voestalpine eifeler Coating GmbH for coating questions.
1. FAILURE TYPE
   Find the dominating wear mechanism

2. TOOLING QUALITY
   Surface finish in active surfaces and other areas exposed to high loads

3. TOOL STEEL AND COATING SELECTION
   Choose steel and/or coating for the dominating wear mechanism

4. HEAT TREATMENT
   Make sure that the heat treatment and coating process fit together

CHOOSE THE RIGHT COMBINATION

When choosing the combination tool steel and PVD coating for a cold work application there are four crucial factors to consider:

1. FAILURE TYPE
   Choose steel with enough chipping resistance
   Choose steel with higher compressive strength (hardness)

2. TOOLING QUALITY
   Solve by substrate
   Solve by coating

3. TOOL STEEL AND COATING SELECTION
   Choose a coating with high hardness and wear resistance
   Choose a coating with fine surface and low friction properties

4. HEAT TREATMENT
   Cracking of coating
   Galling due to cracks initiated in the coating by deep grinding marks

The active areas of the tool should be smooth and free from corrosion and white layers in order to obtain the best performance result. After grinding, a typical surface finish of Ra=0.5 µm is obtained, which is not smooth enough for a high performance tool in cold work application. A rough surface (by e.g. grinding marks) may lead to inhomogeneous coating layers and cracks in the PVD coating. Thus, polishing to Ra <0.2 µm is recommended before a PVD coating is applied. For critical applications, even finer Ra <0.05 µm. Furthermore, depending on the application, a post-treatment of the coated tool may be recommended and should be discussed with the respective sales contact at voestalpine eifeler Coating GmbH.

**UDDEHOLM PREMIUM COLD WORK STEEL**

**ALLOW THE COATING TO DO ITS JOB IN THE BEST WAY**

The Uddeholm premium cold work steels have been found to be particularly suitable for PVD coatings. The uniform microstructure and high cleanliness in these steels facilitate bonding of the coating and reduces the spread of dimensional changes resulting from hardening. This, together with the material's high strength allows the coating to do its job in the best way.

The active areas of the tool should be smooth and free from corrosion and white layers in order to obtain the best performance result. After grinding, a typical surface finish of Ra=0.5 µm is obtained, which is not smooth enough for a high performance tool in cold work application. A rough surface (by e.g. grinding marks) may lead to inhomogeneous coating layers and cracks in the PVD coating. Thus, polishing to Ra <0.2 µm in active areas is recommended before a PVD coating is applied. For critical applications, even finer Ra <0.05 µm. Furthermore, depending on the application, a post-treatment of the coated tool may be recommended and should be discussed with the respective sales contact at voestalpine eifeler Coating GmbH.

**SURFACE**

Surface profile with deep grinding marks, Ra=0.5 µm, Rz=4.0 µm

**CRACKING**

Galling due to cracks initiated in the coating by deep grinding marks

Cracks in the remelted white layer after EDM

Heat affected surfaces from WEDM need to be removed and 3–4 passes are needed to reduce the heat affected zone that have small cracks and high stress level.

4. HEAT TREATMENT
The most important part of the heat treatment is to temper the steel at a temperature higher than both the coating process (typically 450°C) and the retained austenite area (see diagram to the right).

A common problem with standard AISI D2 tool steel is dimensional growth, due to the usage of a low tempering temperature (~500-510°C) for keeping a high hardness. Retained austenite will remain in the microstructure and this will transform into martensite during the coating process or in use of the tool. This results in a volume expansion of the tool, which may exceed the desired geometrical tolerances.

Due to a relatively wide range in chemical composition of a AISI D2 steel the minimum tempering temperature for avoiding retained austenite is not well defined. Hence a safe margin is necessary.

For more details see technical product brochures for the steel grades.

**UDDEHOLM TOOL STEEL IN COMPONENTS**

ALLOW THE COATING TO DO ITS JOB IN THE BEST WAY

By using premium Uddeholm tool steel in components, you will increase the productivity and extend the time between maintenance. By adding a suitable PVD coating the life of the component can be increased even further.

**MEAT PROCESSING**

Hole plates in Uddeholm Vanadis® 4 Extra SuperClean + VARIANTIC coating is an excellent choice for mincing of meat.

- The combination of high hardness and low friction gives a long tool life
- Less maintenance and higher productivity

Uddeholm steel grades and coatings from voestalpine stierler Coating GmbH are certified acc. to EC No 1935/2004 for food contact.
It is important to choose the right steel grade for the moulding since plastic moulding is a demanding process.

UDDEHOLM CAN OFFER DIFFERENT TYPES OF MOULD STEEL FOR PLASTIC MOULDING
- Prehardened mould and holder steel.
- Through-hardened mould steel.
- Corrosion resistant mould steel.

PVD coating of plastic moulds is a way to improve the mould life for moulds used for injection moulding, extrusion, vacuum forming and blow moulding. It is important to have a good support material with sufficient hardness, uniform microstructure and cleanliness for a successful PVD coating. Uddeholm plastic mould steels fulfill these demands and thus make an excellent choice for PVD coating.

FAILURES THAT CAN BE SOLVED BY THE STEEL
- Cracks and/or gross cracking caused by high static or dynamic loads. The solution in this case is an upgrade to a steel grade with a better toughness.
- Plastic deformation due to loads higher than the yield strength of the material can only be solved by choosing a steel with a higher hardness.

FAILURES THAT CAN BE SOLVED BY PVD COATING
- Abrasive wear caused by hard particles in the plastic resin like glass fibre.
- Release problem due to sticking of plastic.
- Adhesive wear, galling between sliding parts.
- Diesel effect, corrosive off-gassing created by plastic material such as PVC or halogenated or halogen free fire retardants.
- Problem to clean, due to that additives like fire retardants cause deposits to stick on the mould cavity surface.

EXAMPLE OF SUITABLE PVD COATINGS FOR PLASTIC MOULDING
When choosing a hot work tool steel suitable for hot work applications the properties of that steel are very important. There are many different applications within hot work, such as HPDC (High Pressure Die Casting), Forging, Extrusion and Hot stamping. These different segments have very different demands on the tool steel. Therefore the correct tool steel must be selected, as certain steels can solve these issues better than others.

**Desirable Properties Needed in Hot Work**

- Good ductility
- High hot strength
- Good temper resistance
- High hot hardness

**Failures That Can Be Solved by the Steel**

- Gross cracking, heat checking and indentations are failures which can be solved or reduced by changing the steel grade or the hardness level.

**Failures That Can Be Solved by PVD Coating**

- Erosion, corrosion or soldering problems on cores, ejector pins and cavities (with simple geometry).
- Abrasive wear in Hot Stamping.

### Example of Coatings for Hot Work Steels

<table>
<thead>
<tr>
<th>Coating</th>
<th>Coating Type</th>
<th>Colour</th>
<th>Key Properties</th>
<th>Thermal Limit</th>
</tr>
</thead>
</table>
| CROSAL® - plus   | AK/TiN       | Slate grey | • High oxidation resistance  
• Outstanding hot hardness            | 1100°C (2012°F) |
| Duplex - TIGRAL® | AK/TiN       | Grey     | • High hot hardness  
• Excellent oxidation resistance  
• Excellent abrasion resistance     | 800°C (1470°F)  |
| Duplex - VARIANTIC® | TiAlCN     | Old rose | • Good chemical resistance  
• Low friction  
• Good oxidation resistance in semi-warm-forming |                     |

Not all application areas are suitable for coatings as each tool must be judged on it’s merits. However, targeted use of certain coatings can help extend die life. An example would be in HPDC with waterjacket inserts and core pins. When selecting a coating or surface treatment, the hardness levels should be over >48 HRC to achieve the best possible surface finish.
